

Clarify Your Understanding On Laser Eye Surgery

It seems that just about everywhere you turn these days people are talking about laser eye surgery. And, even while it is being mentioned in different types of media and discussed between people, there are many left to wonder exactly what this high-tech procedure is and what kind of vision problems it can successfully correct. Following is some basic information about this corrective eye surgery, which can serve as an introduction to the topic. The most common type of laser vision surgery is called Lasik eye surgery and it does have some aspects that set it apart from other types of surgery to correct vision problems. The main distinction is that the Lasik procedure does not require the doctor to actually cut the cornea surface. This means that there are generally few complications with this kind of eye surgery and the risks to the patient and their vision is also very low. The term Lasik is an acronym that stands for "Laser In-Situ Keratomileusis." By utilizing a laser light, the surgeon is able to carry out the corrective procedure while leaving the surface of the eye lens completely intact and unharmed. This type of laser eye surgery provides a huge advantage over the older, traditional methods which often caused damage to the lens surface through the use of surgical instruments. Lasik laser eye surgery has become one of the most widely used and popular methods to correct vision problems. This corrective eye surgery is best suited for those who are near-sighted, who are far-sighted, and for those who have an astigmatism, which are all vision conditions that affect a significant portion of the aging, baby boomer population. Lasik eye surgery is able to reshape the cornea of the eye, which is the outer layer, or covering. When this is done properly by the Lasik eye doctor, the light which passes through the cornea is better focused onto the retina at the back of the eye, which is essentially where the vision "signals" are interpreted. In addition to being overwhelmingly effective, another advantage of this remarkable procedure is that the patient who undergoes the treatment experiences very little discomfort. Also, after the Lasik corrective eye surgery, the vision is noticeably improved almost instantly and there is no need to have the eyes bandaged, nor is there any need for stitches. These various factors all combine to provide the patient with a fast recovery and with an extremely low risk of any kind of complications or infection, which were actually quite commonplace before laser eye surgery became available. The cost of Lasik surgery can be at least partially covered by many vision insurance plans. However, even for those who do not enjoy such coverage, the cost of Lasik is quite minimal compared to the enormous benefits they receive from the procedure.
